Interactive Relationships

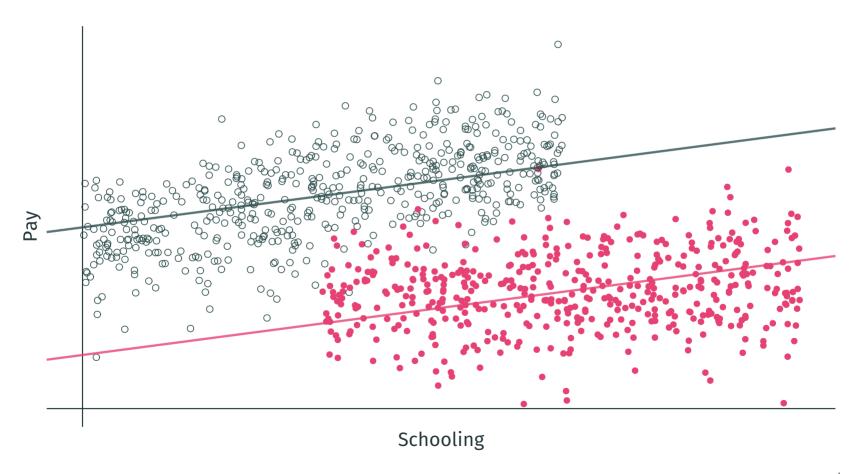

EC 320: Introduction to Econometrics

Kyle Raze Fall 2019

Prologue

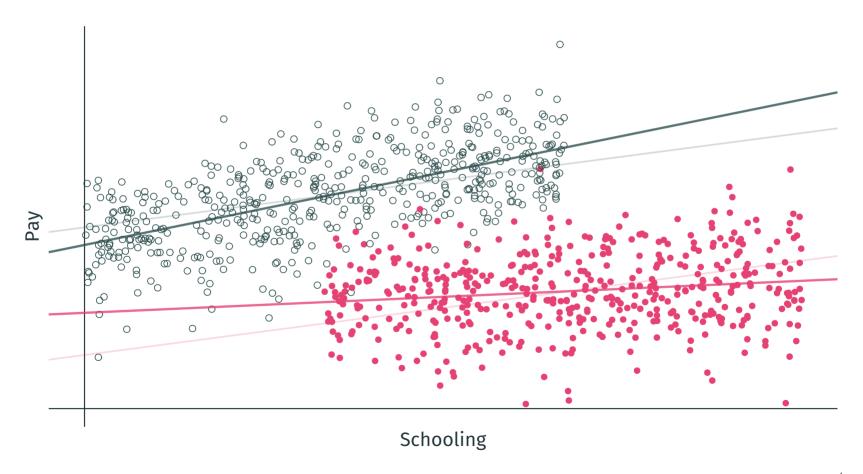

Last Time

We considered a model where schooling has the same effect for everyone (**F** and **M**):

Today

We will consider models that allow effects to differ by another variable (e.g., by gender: **F** and **M**):

Interactive Relationships

Motivation

On average? For whom?

Regression coefficients describe average effects.

• Averages can mask heterogeneous effects that differ by group or by the level of another variable.

We can use interaction terms to model heterogeneous effects.

• Accommodate complexity and nuance by going beyond "the effect of X on Y is eta_1 ."

Interaction Terms

Starting point:
$$Y_i = eta_0 + eta_1 X_{1i} + eta_2 X_{2i} + u_i$$

- X_{1i} is the variable of interest
- X_{2i} is a control variable

A richer model: Add an interaction term to study whether X_{2i} moderates the effect of X_{1i} :

$$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{1i} \cdot X_{2i} + u_i$$

Interpretation: The partial derivative of Y_i with respect to X_{1i} is the marginal effect of X_1 on Y_i :

$$\frac{\partial Y}{\partial X_1} = \beta_1 + \beta_3 X_{2i}$$

• Effect of X_1 depends on the level of X_2

Research Question: Do the returns to education vary by race?

Consider the interactive regression model

$$\mathrm{Wage}_i = \beta_0 + \beta_1 \mathrm{Education}_i + \beta_2 \mathrm{Black}_i + \beta_3 \mathrm{Education}_i \times \mathrm{Black}_i + u_i$$

What is the marginal effect of an additional year of education?

$$\frac{\partial \text{Wage}}{\partial \text{Education}} = \beta_1 + \beta_3 \text{Black}_i$$

```
lm(wage ~ educ + black + educ:black, data = wage2) %>% tidy()
```

What is the **return to education** for **black** workers?

$$\left. \left(rac{\partial \widehat{ ext{Wage}}}{\partial ext{Education}}
ight)
ight|_{ ext{Black}=1} = \hat{eta}_1 + \hat{eta}_3 = 17.65$$

```
lm(wage ~ educ + black + educ:black, data = wage2) %>% tidy()
```

What is the **return to education** for **non-black** workers?

$$\left. \left(\frac{\partial \widehat{\mathrm{Wage}}}{\partial \mathrm{Education}} \right) \right|_{\mathrm{Black}=0} = \hat{eta}_1 = 58.38$$

Q: Does the return to education differ by race?

• For answer, conduct a two-sided *t* test of the null hypothesis that the interaction coefficient equals 0 at the 5% level.

```
lm(wage ~ educ + black + educ:black, data = wage2) %>% tidy()
#> # A tibble: 4 x 5
#>
   term estimate std.error statistic p.value
#>
  <chr>
             <dbl>
                    <dbl>
                               <dbl> <dbl>
#> 1 (Intercept) 196. 82.2 2.38 1.75e- 2
#> 2 educ
         58.4 5.96 9.80 1.19e-21
#> 3 black
          321.
                      263. 1.22 2.23e- 1
#> 4 educ:black -40.7
                       20.7
                               -1.96 4.99e- 2
```

p-value = 0.0499 < 0.05 \Rightarrow reject null hypothesis.

A: The return to education is significantly lower for black workers.

We can also test hypotheses about specific marginal effects.

• e.g.,
$$H_0$$
: $\left(\frac{\partial \text{Wage}}{\partial \text{Education}}\right)\Big|_{\text{Black}=1} = 0$.

Conduct a t test or construct confidence intervals.

Problem 1: lm() output does not include standard errors for the marginal effects.

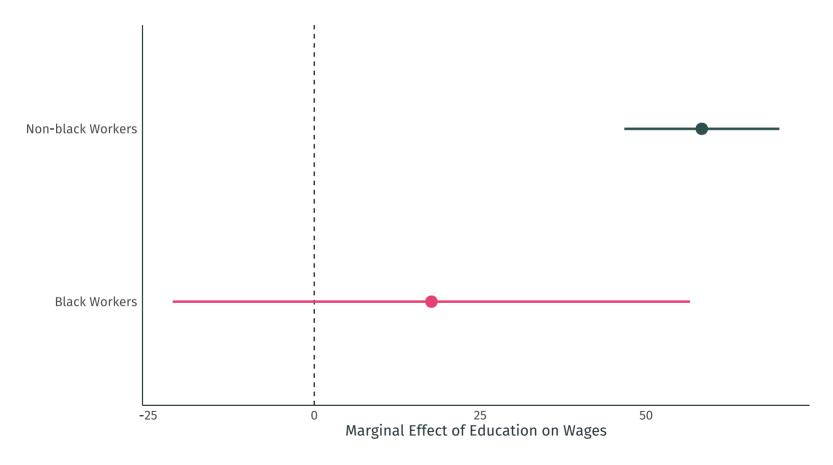

Problem 2: The formula for marginal effect standard errors includes covariances between coefficient estimates. The math is messy.[†]

Solution: Construct confidence intervals using the margins package.

The margins function provides standard errors and 95% confidence intervals for each marginal effect.

Marginal effect of education on wages for black workers.

We can use the <code>geom_pointrange()</code> option in <code>ggplot2</code> to plot the marginal effects with 95% confidence intervals.

We can use the <code>geom_pointrange()</code> option in <code>ggplot2</code> to plot the marginal effects with 95% confidence intervals.

Research Question: Does the effect of school spending on student achievement vary by the share of students experiencing poverty?

• Does the marginal dollar go further in a school with a relatively affluent student body?

Regression Model

$$\mathrm{Read}_i = eta_0 + eta_1 \mathrm{Spend}_i + eta_2 \mathrm{Lunch}_i + eta_3 \mathrm{Spend}_i imes \mathrm{Lunch}_i + u_i$$

- Read_i is the average fourth grade standardized reading test score in school i (100-point scale).
- \mathbf{Spend}_i measured as thousands of dollars per student.
- Lunch_i is the percentage of students on free or reduced-price lunch.

Regression Model

```
\mathrm{Read}_i = eta_0 + eta_1 \mathrm{Spend}_i + eta_2 \mathrm{Lunch}_i + eta_3 \mathrm{Spend}_i 	imes \mathrm{Lunch}_i + u_i
```

Results

```
lm(read4 ~ spend + lunch + spend:lunch, data = meap01) %>% tidy()
```

Results

```
lm(read4 ~ spend + lunch + spend:lunch, data = meap01) %>% tidy()
```

What is the estimated marginal effect of an additional 1000 dollars per student?

$$\frac{\widehat{\partial \mathrm{Read}}}{\partial \mathrm{Spend}} = \hat{\beta}_1 + \hat{\beta}_3 \mathrm{Lunch}_i$$

Q: Does the effect of school spending on student achievement vary by the share of students experiencing poverty?

If the marginal effects do not vary by poverty levels, then

$$egin{aligned} rac{\partial ext{Read}}{\partial ext{Spend}} &= eta_1 + eta_3 ext{Lunch}_i \ &= eta_1 \end{aligned}$$

$$H_0$$
: $\beta_3=0$ vs. H_a : $\beta_3\neq 0$

• Can evaluate using a t test or an F test.

Conduct a two-sided t test at the 10% level

H₀:
$$\beta_3=0$$
 vs. **H_a:** $\beta_3\neq 0$

$$t = -2.44$$
 and $t_{0.95, 1823-4} = 1.65$

Reject
$$\mathbf{H_0}$$
 if $|t| = |-2.44| > t_{0.95, 1823-4} = 1.65$.

Statement is true \Rightarrow reject H_0 at the 10% level.

Conduct an F test at the 10% level

```
reg unrestrict ← lm(read4 ~ spend + lunch + spend:lunch, data = meap01)
 reg restrict \leftarrow lm(read4 \sim spend + lunch, data = meap01)
 anova(reg unrestrict, reg restrict)
#> Analysis of Variance Table
#>
#> Model 1: read4 ~ spend + lunch + spend:lunch
#> Model 2: read4 ~ spend + lunch
     Res.Df RSS Df Sum of Sq F Pr(>F)
#>
#> 1 1819 408262
#> 2 1820 409596 -1 -1334 5.9434 0.01487 *
#> ---
#> Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
H<sub>0</sub>: \beta_3=0 vs. H<sub>a</sub>: \beta_3\neq 0
p-value = 0.01487 < 0.1 \Rightarrow reject H_0 at the 10% level.
```

Q: Is there a statistically significant effect of spending on student achievement for every level of poverty?

One way to answer this question is to construct confidence intervals for the marginal effects.

- Requires standard errors.
- Standard errors will depend on the poverty level (our proxy: Lunch_i).

Time for math! 🦠

Step 1: Derive the estimated marginal effects.

$$\frac{\widehat{\partial \mathrm{Read}}}{\partial \mathrm{Spend}} = \hat{\beta}_1 + \hat{\beta}_3 \mathrm{Lunch}_i$$

Step 2: Derive the variances of the estimated marginal effects.

$$\begin{split} &\operatorname{Var}\!\left(\frac{\widehat{\partial \mathrm{Read}}}{\partial \mathrm{Spend}} \right) \\ &= \operatorname{Var}\!\left(\hat{\beta}_1 + \hat{\beta}_3 \mathrm{Lunch}_i \right) \\ &= \operatorname{Var}\!\left(\hat{\beta}_1 \right) + \operatorname{Var}\!\left(\hat{\beta}_3 \mathrm{Lunch}_i \right) + 2 \cdot \operatorname{Cov}\!\left(\hat{\beta}_1, \ \hat{\beta}_3 \mathrm{Lunch}_i \right) \\ &= \operatorname{Var}\!\left(\hat{\beta}_1 \right) + \operatorname{Lunch}_i^2 \cdot \operatorname{Var}\!\left(\hat{\beta}_3 \right) + 2 \cdot \operatorname{Lunch}_i \cdot \operatorname{Cov}\!\left(\hat{\beta}_1, \ \hat{\beta}_3 \right) \\ &= \operatorname{SE}\!\left(\hat{\beta}_1 \right)^2 + \operatorname{Lunch}_i^2 \cdot \operatorname{SE}\!\left(\hat{\beta}_3 \right)^2 + 2 \cdot \operatorname{Lunch}_i \cdot \operatorname{Cov}\!\left(\hat{\beta}_1, \ \hat{\beta}_3 \right) \end{split}$$

Step 3: Derive the standard errors of the estimated marginal effects.

$$\begin{split} &\operatorname{SE}\left(\frac{\widehat{\partial \operatorname{Read}}}{\partial \operatorname{Spend}}\right) \\ &= \operatorname{Var}\left(\frac{\widehat{\partial \operatorname{Read}}}{\partial \operatorname{Spend}}\right)^{1/2} \\ &= \sqrt{\operatorname{SE}\left(\widehat{\beta}_1\right)^2 + \operatorname{Lunch}_i^2 \cdot \operatorname{SE}\left(\widehat{\beta}_3\right)^2 + 2 \cdot \operatorname{Lunch}_i \cdot \operatorname{Cov}\left(\widehat{\beta}_1, \ \widehat{\beta}_3\right)} \end{split}$$

Step 4: Calculate the bounds of the confidence interval.

$$egin{aligned} \hat{eta}_1 + \hat{eta}_3 \cdot \mathrm{Lunch}_i \ &\pm t_{\mathrm{crit}} \cdot \sqrt{\mathrm{SE}\left(\hat{eta}_1
ight)^2 + \mathrm{Lunch}_i^2 \cdot \mathrm{SE}\left(\hat{eta}_3
ight)^2 + 2 \cdot \mathrm{Lunch}_i \cdot \mathrm{Cov}\left(\hat{eta}_1, \ \hat{eta}_3
ight)} \end{aligned}$$

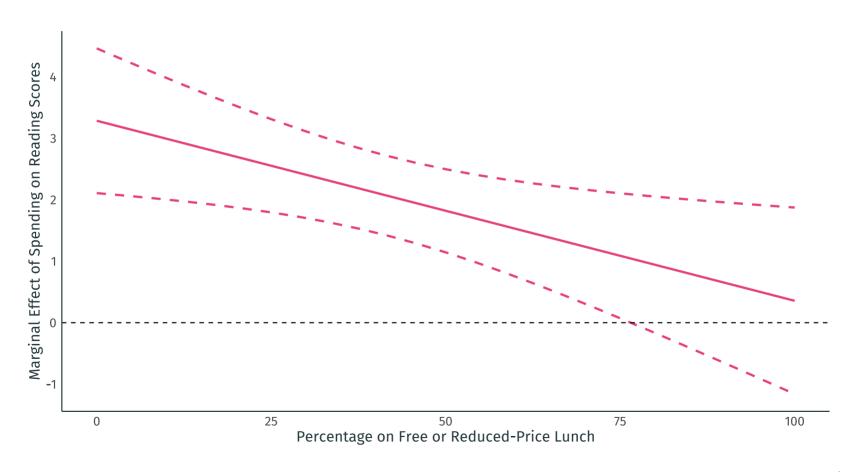

Confidence Interval

$$egin{aligned} \hat{eta}_{1} + \hat{eta}_{3} \cdot \mathrm{Lunch}_{i} \ & \pm t_{\mathrm{crit}} \cdot \sqrt{\mathrm{SE}\left(\hat{eta}_{1}
ight)^{2} + \mathrm{Lunch}_{i}^{2} \cdot \mathrm{SE}\left(\hat{eta}_{3}
ight)^{2} + 2 \cdot \mathrm{Lunch}_{i} \cdot \mathrm{Cov}\left(\hat{eta}_{1}, \ \hat{eta}_{3}
ight)} \end{aligned}$$

Notice that $\operatorname{Cov}\!\left(\hat{\beta}_1,\ \hat{\beta}_3\right)$ is not reported in a regression table

- Located in the variance-covariance matrix inside lm() object (beyond the scope of this class).
- Can't calculate by hand without about $\operatorname{Cov}(\hat{\beta}_1,\ \hat{\beta}_3)$.
- Special case: $\hat{\beta}_1$ and $\hat{\beta}_3$ are statistically independent \Rightarrow $\mathrm{Cov}\Big(\hat{\beta}_1,\ \hat{\beta}_3\Big)=0.$

We can use the cplot function from margins with ggplot2 to plot the marginal effects with 95% confidence intervals.

We can use the cplot function from margins with ggplot2 to plot the marginal effects with 95% confidence intervals.

```
# run regression
reg ← lm(read4 ~ spend + lunch + spend:lunch, data = meap01)
# retrieve marginal effects with 95% CI
margs \leftarrow cplot(reg, x = "lunch", dx = "spend",
               what = "effect", draw = FALSE)
# plot the marginal effects
margs %>%
  ggplot(aes(x = xvals)) +
  geom line(aes(y = yvals)) +
  geom_line(aes(y = upper), linetype = 2) +
  geom line(aes(y = lower), linetype = 2) +
  geom hline(yintercept = 0, linetype = 3) +
  xlab("Percentage on Free or Reduced-Price Lunch") +
  vlab("Marginal Effect of Spending on Reading Scores")
```

Background

Policy Question: How can we lift people out of poverty?

Research Agenda: What kinds of social assistance programs have lasting effects on upward mobility?

Economists study a variety of state and federal social assistance programs.

- Medicaid, SNAP (food stamps), TANF (cash welfare), WIC (benefits for mothers), National School Lunch Program, public housing, Section 8 (housing vouchers), etc.
- Considerable variation in benefits and incentive structures.
- Today: Section 8 v.s. public housing.

Experiment

Research Question: Does moving from a public housing project to high-opportunity neighborhood improve well-being?

Social Experiment: Moving to Opportunity (MTO)

4600 low-income families living in federal housing projects.

- Recruited by the Department of Housing and Urban Development during the mid-1990s.
- Housing projects in Baltimore, Boston, Chicago, Los Angeles, and New York.
- Randomly assigned various forms of housing assistance.

Experiment

Experimental Design

Participants randomly assigned into one of three treatments:

- **Experimental group:** Housing voucher for low-poverty neighborhoods only + counseling
- Section 8 group: Housing voucher for any neighborhood + no counseling
- **Control group:** No housing voucher + no counseling (*i.e.,* regular public housing)

Experiment

Initial Results

- 1. Most families in the treatment groups actually used vouchers to move to better neighborhoods.
- 2. Improvements in physical and mental health.
- 3. No significant improvements in earnings or employment rates for parents.

Experiment

What about children?

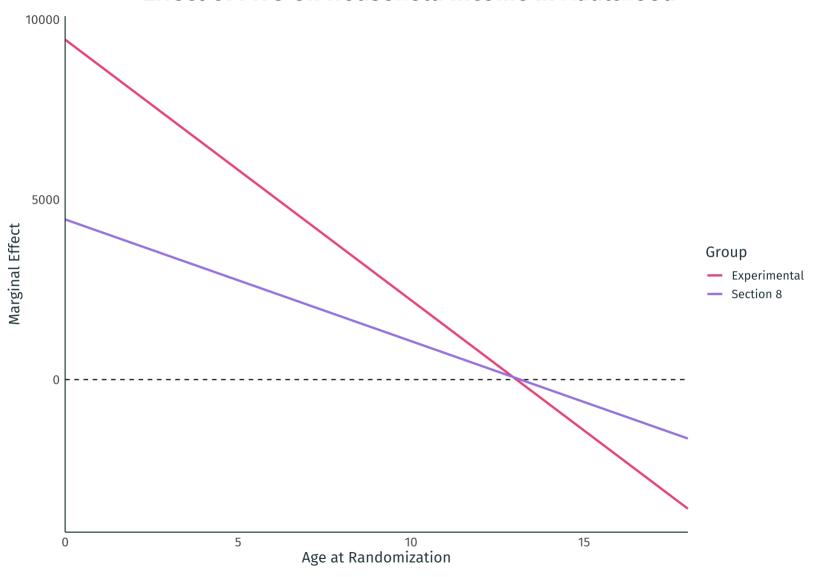

Chetty, Hendren, and Katz (American Economic Review, 2016) study the long-run impact of MTO on children.

- Individual tax data linked to children from original MTO sample.
- Adulthood outcomes: income, marriage, poverty rate in neighborhood of residence, taxes paid, etc.
- Test how effects vary by age of child when family received voucher.

Long-Run Effects of MTO Experiment

	Household Income (\$)	Married (%)	Neighborhood Poverty (%)	Taxes Paid (\$)
Experimental	9441.1	8.309	-4.371	831.2
	(3035.8)	(3.445)	(1.770)	(279.4)
